- 5 Conclusions and perspectives

Outline

- 1 Context
- 2 Proposed approach
- 3 Prototype
- 4 Experiments and preliminary evaluation
- 5 Conclusions and perspectives

Context

- Linked Open Data (LOD) as large RDF interlinked data collection
- Emergent need to exploit LOD for analytical analysis
- *Online Analytical Processing* (OLAP) as a potential alternative for manipulating these data : aggregating, summarising and filtering

Dimensions : subjects of analysis (Product,Geography,Time)
Hierarchies : axes of analysis (Continent ← Country ← City)

Objectives

- Manipulate OLAP operations on RDF data without any ETL (Extract, Transform, Load) process
- Focus on RDF data described using the RDF Data Cube vocabulary
- Represent multiples hierarchies in a dimension
 - Country \leftarrow Region \leftarrow City
 - Area \leftarrow City
- Take into account the special case of *non-covering* hierarchies (at instance level)
 - Continent \leftarrow Country \leftarrow City (Toulouse)
 - Continent \leftarrow City (Monaco)

Outline

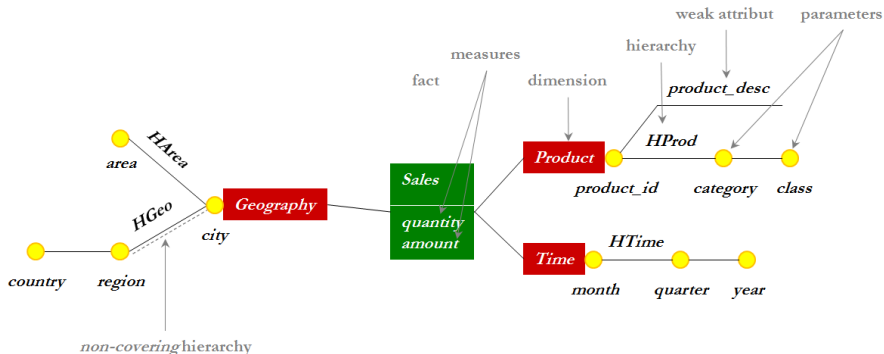

- 1 Context
- 2 Proposed approach**
- 3 Prototype
- 4 Experiments and preliminary evaluation
- 5 Conclusions and perspectives

Proposed approach

- Formalise a multidimensional structure
 - following a constellation model [Ravat et al., 2008]
 - where facts and dimensions composed of multi-hierarchies
 - weak attributes complete the information on a hierarchy
- Define a mechanism for translating OLAP operations into SPARQL queries
 - based on a query algebra compliant with the constellation model
 - focus on main OLAP operations (*Drilldown*, *Rollup*, *Select*, *Rotate*)

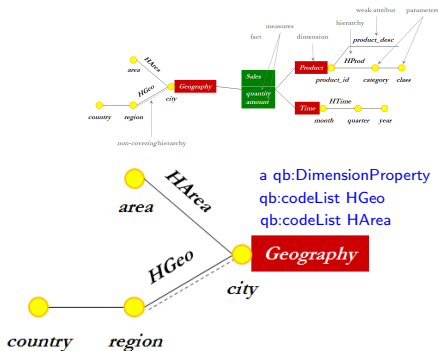

Constellation Model on RDF

- Constellation schema as conceptual model for defining the elements of a multidimensional model in terms of RDF
- Definition of dimensions D , hierarchies H , facts F and constellation of facts C_s , using as basis the vocabularies RDF Data Cube, SKOS and RDFS

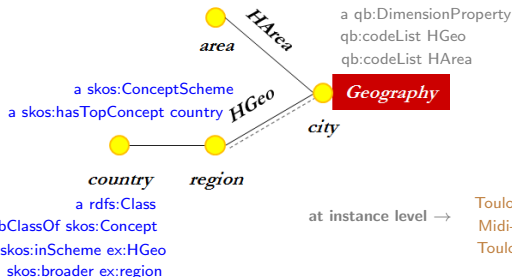

Constellation Model on RDF : dimensions

- A dimension models an axis of analysis and contains one or more hierarchies

Constellation Model on RDF : hierarchies

- A hierarchy represents levels of granularity from which measures are analysed

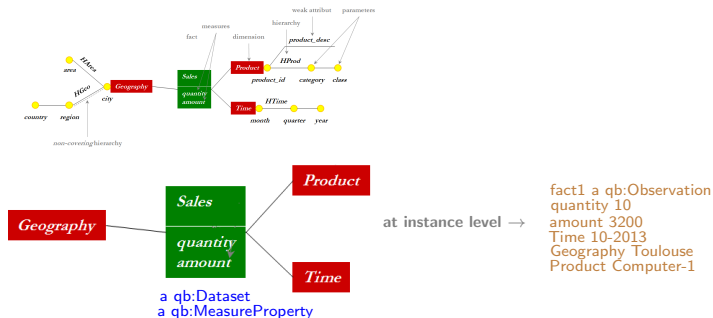

at instance level →

Toulouse a city
 Midi-Pyrennes a region
 Toulouse skos:broader Midi-Pyrennes

Constellation Model on RDF : facts

- A fact reflects the information to be analysed according to dimensions and measures
- Values of fact instances (observations) correspond to the lowest level of hierarchies for each dimension

Translating OLAP Operations into SPARQL

- Mechanism based on a query algebra compliant to the constellation model
- This algebra relies on a graphical multidimensional table (MT)

S = represents the analysed subject through facts (aggregations)

L = horizontal analysis axis (dimension)

C = vertical analysis axis (dimension)

R = restrictions of dimensions and fact data (filters)

- Each OLAP operation has an input MT_{SRC} and an output MT_{RES}
- Each MT_{RES} can further be manipulated using operators of the same algebra
- Initial MT is built from a constellation Cs , using the operator *Display*

Translating OLAP Operations into SPARQL

Table result

Query

Display operation

- Display the root parameters of each hierarchy (lowest level of each dimension hierarchy) :
 - Identify the fact instances and retrieve root values PL_1 (horizontal) and PC_1 (vertical) of the dimensions DL and DC
 - Retrieve the value mv_i of each measure m_i and group mv_i by PL_1 and PC_1
 - Calculate the aggregations by applying to mv_i the aggregation functions Agg_i

```

SELECT ?PL1 ?PC1 (Aggi(mvi) AS ?mesi)
WHERE
{
  ?obs rdf:type qb:Observation.
  ?obs qb:dataset IRI(FS).
  ?obs IRI(DL) ?PL1.
  ?obs IRI(DC) ?PC1.
  ?obs IRI(mi) ?mvi.
}
GROUP BY ?PL1 ?PC1

```

```

SELECT ?prodId ?city (SUM(?qty)
AS qtySales) WHERE
{
  ?obs rdf:type qb:Observation.
  ?obs qb:dataset ex:Sales.
  ?obs ex:Products ?prodId.
  ?obs ex:Geography ?city.
  ?obs ex:quantity ?qty.
}
GROUP BY ?prodId ?city

```

Hierarchy : Country - Region - City

Rollup and Drilldown operations

- Provide results by different hierarchical levels
- Use *skos:broader* to navigate between levels
- Recalculates all aggregations from the lowest hierarchical level (no pre-aggregations)

Hierarchy : Country - **Region** - City

```

SELECT ?prodId ?region (SUM(?qty) AS qtySales)
WHERE
{
  ?obs rdf:type qb:Observation.
  ?obs qb:dataset ex:Sales.
  ?obs ex:Product ?prodId.
  ?obs ex:Geography ?city.
  ?city skos:broader ?region.
  ?region skos:inScheme ex:HGeo.
  ?region rdf:type ex:Region.
  ?obs ex:quantity ?qty.
}
GROUP BY ?prodId ?region
  
```

Rollup and Drilldown : non covering hierarchies

- Not all instances respect the hierarchy
 - Europe \leftarrow France \leftarrow Toulouse (Europe in level 3)
 - Europe \leftarrow Monaco (Europe in level 2)
- May generate wrong aggregation results
- Use UNION operator

```

SELECT ?prodId ?country (SUM(?qty)
AS ?SalesQty)
WHERE
{
  ?obs rdf:type qb:Observation.
  ?obs qb:dataset ex:Sales.
  ?obs ex:quantity ?qty.
  ?obs ex:Products ?prodId.
  ?country rdf:type ex:Country.
  {
    ?obs ex:Geography ?geo1.
    ?geo1 skos:broader ?geo2.
    ?geo2 skos:inScheme ex:HGeo.
    ?geo2 skos:broader ?country.
  }
}
UNION
{
  ?obs ex:Geography ?geo1.
  ?geo1 skos:broader ?country.
}
UNION
{
  ?obs ex:Geography ?country.
}
GROUP BY ?prodId ?country

```

Outline

- 1 Context
- 2 Proposed approach
- 3 Prototype**
- 4 Experiments and preliminary evaluation
- 5 Conclusions and perspectives

Prototype

- Implemented using Microsoft .NET framework and dotNetRDF API

The screenshot shows the 'RDF OLAP' application window. It features a 'qb Data Structure Definition' section with a text box containing 'D:\exprim\DSDD.ttl' and a dropdown menu set to 'http://example.org/dsdSalesCube'. The 'qb Data Set' section has a text box with 'D:\exprim\generatedRDF.ttl' and a dropdown menu set to 'http://example.org/Sales'. To the right are buttons for 'Display', 'RollUp', 'DrillDown', 'Rotate', 'Select', and 'Unselect'. Below these is a table with three columns: 'IdProduct', 'Date', and 'Quantity'. The table contains 18 rows of data. To the right of the table is a query editor showing an SPARQL query. At the bottom of the window, it displays 'Temps d'exécution : 3,5596735 sec'.

Outline

- 1 Context
- 2 Proposed approach
- 3 Prototype
- 4 Experiments and preliminary evaluation**
- 5 Conclusions and perspectives

Experiments and evaluation

• Data sets

- Real data : Annual producer price of industrial products from CA 1996 Statistical Office of the Republic of Serbia
 - 789 instances of attributes and 156 observations
 - 1 temporal and 1 geographical (about Serbia) dimensions
 - Observations modified for generating non-covering instances data
- Synthetic data
 - 69888 observations and 1191 instances of attributes

• (Very) Preliminary evaluation

- Limited to manipulations of OLAP operations on these two data sets
- Adequacy and correctness of results from a sequence of operations
- No measurements on runtime

Outline

- 1 Context
- 2 Proposed approach
- 3 Prototype
- 4 Experiments and preliminary evaluation
- 5 Conclusions and perspectives**

Conclusions and perspectives

- Formalisation of a constellation model in terms of RDF data
- Mechanism for translating OLAP operations into SPARQL
- Handling special cases where hierarchies are not fully covered at instance level
- Perspectives : improve visualisation, expressing advanced OLAP operations, query optimisation and pre-aggregations, exploitation of links (data across data sets).
